INTRODUCTION. Cutaneous elastosis with cysts and comedones (Favre-Racouchot) is one of the oldest known manifestations of helioderma. Both sides of the face are usually involved symmetrically. CASE REPORT. We observed a 65-year-old woman with extremely severe Favre-Racouchot disease localized exclusively on the left side of the face. The diagnosis of elastosis with cysts and comedones was confirmed histologically. This elastosis with cysts and comedones was associated with spasms of the hemiface treated with injections of ***botulinic*** toxin. This association was fortuitous and we retained actinic irradiation as the causal agent in this woman who had worked for 15 years in the same room. The elastosis occurred on the side of the face which had been continuously exposed at the same orientation to the window. COMMENTS. This original observation is

similar to cases where facial exposure to artificial light or sunlight is asymmetrical, leading to a higher incidence of lesions on one side of the face: colloid milium, actinic keratosis; Dubreuilh melanoma (malignant ***lentigo***) or simple helioderma. The asymmetrical nature of the actinic lesions is often related to automobile driving. This case was particular since it demonstrated that Favre-Racouchot elastosis with cysts and comedones is due to actinic irradiation and not to skin aging.

A severe neurological disorder was observed during a very dry season, in sheep pasturing on land with mediterranean vegetation. During the crisis, lasting 5-20", ataxia and convulsions were the main clinical signs. Brain congestion, spongy appearance of the liver, interstitial nephritis and **hyperpigmentation** of visceral lymph nodes were the most important macroscopic lesions. Histopathological, histochemical and ultrastructural findings confirmed liver and kidney lesions and showed considerable neurovisceral storage of lipofuscin. Although further toxicological and experimental studies are needed to elucidate the origin of the disease, the Authors attribute the outbreak of the neurological syndrome to the ingestion of a ***neurotoxin*** containing plant.

Numerous treatments have been described for the treatment and prevention of scars, but the optimal management strategy is yet to be defined. In this article we present and evaluate new opportunities for the treatment and prevention of hypertrophic scars, keloids, and atrophic scars. Clinical, animal, and in vitro studies reporting novel techniques for the treatment and prevention of scarring were identified primarily from the MEDLINE/PubMed database. We found that a variety of new treatments exist with potential effectiveness for the treatment of hypertrophic scars and keloids, including interferon, imiquimod 5% cream, tacrolimus,

botulinum toxin, 5-fluorouracil, bleomycin, and verapamil. For atrophic scars, different types of lasers represent modern treatment modalities with satisfactory results. Several agents have been reported to be effective in reducing scarring in vitro and in animal studies, representing potential opportunities for scarring management. We conclude that several novel modalities may be potential therapies for scarring.

CODEN: KEGEA ISSN: 0021-5228
DOCUMENT TYPE: Journal ; Article
LANGUAGE: JAPANESE SUMMARY LANGUAGE: ENGLISH; JAPANESE
NUMBER OF REFERENCES: 17

Many therapeutic procedures are becoming popular for lip and peripheral rejuvenation. Injectable materials, such as collagens and hyaluronic acid gels, are effective for correcting the rhytides, but diminish over time. Artificial materials can be an option used for upper lip and nasolabial sulcus eversion. Chemical peeling and non-ablative laser resurfacing can improve irregularities of the lip skin. Ablative laser resurfacing is appropriate for rhytides that resist other therapies. ***Botulinum*** toxin type A smooths hyperfunctional lines of the lip. Vbeam(R) laser has the efficacy of the clinically proven pulsed dye laser coupled with an integrated dynamic cooling device that minimizes subsequent erythema and post-inflammatory ***hyperpigmentation***. Finally, autologous fat transfer can be performed for augmentation of the vermillion or the nasolabial sulcus, but its effectiveness depends on the survival of injected adipocytes.

NUMBER OF REFERENCES: 12

As patients become more aware of their options related to facial enhancement, nonsurgical offerings will become an ever larger component of the cosmetic practice. Patients will continue to demand rejuvenating options but will desire a minimum of downtime, discomfort, and invasiveness. The use of traditional skin care approaches such as microdermabrasion, **botulinum** toxin, injectable fillers, and prescription-grade skin care products will be accentuated by the advances in laser and IPL technology. Using these new technologies effectively, knowledgeably, and safely is crucial for the maxillofacial surgeon to maintain the leading role in facial cosmetic surgery. Currently, dozens of lasers exist for noninvasive cosmetic procedures. This wide range of options, with each option having its own claims of efficacy, superiority, and ease of use, is beyond this review. The reader is encouraged to investigate thoroughly any claims, studies, or promises made by any manufacturer. It is wise to test any equipment in the clinic for as long as possible before purchase. A number of the lasers mentioned in this review are those with which the author has had significant experience. Their inclusion is not an endorsement of any individual type of laser or manufacturer. These technologies are not inexpensive to acquire; a complete understanding of the laser's physics, personnel required, and necessary ancillary supplies is mandatory. In addition, local, state, or regional rules and regulations may impact the use of laser technology in any given practice. The noninvasive laser and IPL cosmetic procedures covered in this article are only a few of the uses for lasers in cosmetic maxillofacial surgery. These procedures are part of an overall practice philosophy of which skin care and maintenance is a vital component. In conjunction with prescription skin care products, **botulinum** toxin, microderma brasion, injectable fillers, and so forth, these laser procedures provide a comprehensive menu of services for contemporary maxillofacial surgery practices. Starting a skin care practice takes patience and dedication, but it provides your patients with a necessary service for a comprehensive facial plastic and reconstructive surgery practice. This article discusses the differences between physician-directed skin care and spa-directed skin care and emphasizes procedures that may be performed by an aesthetician in a physician's office. Skin care practice can be classified into skin care regimens: chemical peels, microdermabrasion, and makeup. Optimal skin care regimens incorporate pharmaceutical-grade ingredients, including tretinoin, topical vitamin C, and hydroquinone. Microdermabrasion and superficial chemical peels, such as glycolic, salicylic, and trichloroacetic acid peels, are discussed. Noninvasive procedures by the physician, such as **Botox** and laser treatments, complement the procedures performed by the aesthetician. However, the physician is ultimately responsible for the philosophy of the skin care practice. Patient education, customer service, and skin health are key ingredients for success.

The options available to cosmetic surgeons for the treatment of the aging face are expanding at a rapid pace. Although any one modality may help, often a combination of approaches provides the most dramatic results. Whereas some of these techniques represent refinements of old tools, others represent entirely new modalities (Box 1). To tailor the most effective treatment plan appropriately, the limitations and strengths of these various tools must be understood by the patient and physician. During the preoperative consultation, assessment of a patient's expectations is critical when suggesting a treatment plan. By performing an assessment, the physician and patient can experience increased satisfaction because more optimal results are achieved. (c) 2004 Elsevier Inc. All rights reserved.

The face of the aesthetic patient is changing to be more representative of the ethnic diversity of the United States population. It is imperative that the cosmetic dermatologic surgeon not only understand the concerns of the ethnic aesthetic patient but have an awareness of the unique needs of those with darker skin.

NUMBER OF REFERENCES: 41

Aged skin is the result of the combined processes of intrinsic aging and photoaging. Intrinsic aging is a cellular process that involves the accumulation of chronological genetic changes. Little is understood about how to combat intrinsic aging. Photoaging involves environmental effects, mainly damage from the sun, that can be reduced through a variety of

interventions. Several options exist for improving the appearance of aging skin. We present information about the use of nonablative intense pulsed light technology in addition to **botulinum** toxin type A for eradication of the signs of photoaged skin. A structured clinical approach is outlined.

Easy phytic solution: A new alpha hydroxy acid peel with slow release and without neutralization

Deprez P.

Dr. P. Deprez, Port Grec, 40 Planta Baja, Empuria Brava, Girona Spain

AUTHOR EMAIL: deprez@intercom.es

, (45-51)

; Short Survey

LANGUAGE: ENGLISH SUMMARY LANGUAGE: ENGLISH

NUMBER OF REFERENCES: 8

Alpha hydroxy acetic acids (AHAs) are safe, nontoxic, nonmelanotoxic, and easy to apply. AHAs should be neutralized with a basic solution when it reaches the proper depth, after redness appears but before frosting. Easy Phytic Peel does not need neutralization after application. It allows progressive and sequential actuation of its acid and is nonaggressive. The peel can be repeated until the desired results are obtained.

Cosmetic procedures are becoming increasingly popular with dermatologists. They are used to reverse the effects of aging, to improve the quality of the skin, to augment facial structures, and to improve the patient's appearance in general. They can also be beneficial for certain dermatoses. We present an introduction to cosmetic dermatologic procedures, focusing on chemical peels, **botulinum** toxin injections, and the use of filler substances. Following this review, the reader should have the basic knowledge to consider training to perform such procedures safely and effectively, even if he or she has not done so previously. Several agents are available for chemical peeling, each with unique properties for different therapeutic effects. Superficial peels penetrate the epidermis only and include alpha-hydroxy acids, salicylic acid, low-strength trichloroacetic acid (TCA), and Jessner's solution. These epidermal peels are used to treat mild photoaging and other epidermal dermatoses such as acne vulgaris and are generally performed with the use of a series of peels. Medium-depth peels, such as medium-strength TCA or combination peels that use a superficial and medium-depth agent, extend into the papillary dermis or upper reticular dermis. They can eradicate fine lines and wrinkles, improve color variation, eliminate some actinic keratoses, and correct textural irregularities. Higher-strength TCA and phenol induce deep wounding into the mid-to-deep reticular dermis. These deep peels can be used to help eradicate heavy wrinkles and lines due to chronic photodamage, but their use has largely been replaced by erbium and COSUB2 laser resurfacing. Histologic studies have shown that peeling agents help alter the structure and content of the skin, increase production of collagen and glycosaminoglycans, eliminate solar elastosis, and normalize epidermal atypia. Complications are largely related to infection, pigmentary alteration, delayed healing, and scarring, but appropriate patient screening and prophylaxis can minimize their incidence. ***Botulinum*** toxin injections are used in dermatology for two main purposes: elimination or attenuation of dynamic lines and wrinkles on the face and neck and elimination or attenuation of sweating in the case of hyperhidrosis of the hands, axillae, and/or feet. With an excellent safety profile and proven efficacy, these are popular procedures for patients. The medication is a **neurotoxin** that works by temporarily inhibiting the release of acetylcholine. The administering physician must be familiar with pertinent anatomy with respect to muscles of facial expression, appropriate doses, and injection sites, all of which are covered herein. In addition to being an effective treatment by itself, **botulinum** toxin injections can be combined with other procedures such as laser resurfacing, filler substance injections, facelifts, blepharoplasty, etc, to prolong and improve the results. Filler substances are injected in or below the skin in order to replace lost volume or to increase existing volume. They are frequently used for the nasolabial folds, lips, and perioral area, but they can also be used more extensively, as is the case in pan-facial structural lipoaugmentation. Fillers are occasionally used in nonfacial areas as well, such as in aging dorsal hands or other areas of atrophy. A number of filler

substances are available. The main classes of fillers are bovine collagen, human collagen, polysaccharide fillers, fat, synthetic fillers, and combination filler substances. Most filler substances are temporary in their effect, but some do persist in the skin forever. The treating physician must be familiar with proper selection, handling, location and depth of placement, longevity, costs, benefits, and risks of each substance that he or she uses. The necessary information is covered in this text. This text is intended to be a complete introduction to the above-mentioned cosmetic dermatology procedures. It includes aspects such as history and mechanism of action, but it really focuses on the clinical information necessary to be able to consider performing these procedures. It includes suppliers of products, precise descriptions of how to carry out the procedures, and clinical pearls to help achieve successful outcomes.

Background and Objectives: Non-ablative technologies are playing an increasing role in the management of photoaging. Newer radiofrequency technologies have added to this therapeutic armamentarium. Shorter wavelength technologies are more effective in targeting pilosebaceous vascular and pigmentary alterations while longer wavelength technologies are most effective in wrinkle reduction mediated through dermal remodeling. An overview of the various technologies available to the practicing laser surgeon are outlined in the present review. (c) 2003 Wiley-Liss, Inc.

LANGUAGE: ENGLISH SUMMARY LANGUAGE: ENGLISH

Educating the cosmetic patient is an important task, no less important than educating the patient with a dermatologic disease. However, the cosmetic patient is much more difficult to educate, since there are many treatment options, all of which are elective. Furthermore, the patient will only be satisfied with a result that meets their expectations, which may or may not be realistic. A skin cancer patient is generally satisfied knowing that the margins of the tumor are clear and the chances for recurrence are minimal. Even though a scar is left at the removal site, patients are less demanding about the cosmetic outcome. This is not the case with elective cosmetic procedures. The patient perceives that they had nothing wrong to start with and if the outcome is less than expected the failure is much more dramatic. This means that cosmetic patients must be educated with great care and understanding. The best educated patient will be the most satisfied patient in many cases.

In this article, the most common cutaneous manifestations of photodamage

and chronological aging, with the exception of invasive malignancies, are reviewed. Current nonsurgical approaches to the amelioration of the manifestations are discussed, including application of various topical preparations, noninvasive physical and chemical procedures for removal of proliferative lesions, and the options for soft-tissue augmentation.

TEXT:

Thought you'd heard it all when it came to skin care solutions? Think again. Just when it seemed that the beauty industry had exhausted every possible recipe for achieving a more youthful complexion, along comes a new crop of highly innovative (if mind-bogglingly complicated) treatments. So get to know your adenosine triphosphates and kojic acids--they may just be a girl's best friend.

BOTOX LITE

Long before the FDA approved **Botox**--the expression-halting substance that has been injected into millions of frowns, furrows and crow's-feet--for cosmetic purposes last April, skin care laboratories were quietly toiling away, hoping to capture the syringe's magic in cream form. Several creams have recently been introduced with formulas that would make a chemistry major dizzy. But before you scream "Snake oil!" let's not forget the skepticism with which **Botox** was initially received--and the fact that last year alone, half a million people braved the needle, a 67 percent increase from 2001.

First out of the gate is Doctor's Dermatologic Formula (DDF), with goals so similar to **Botox** that the product was cleverly named Faux-Tox. However, the brass at Allergan Inc., ***Botox***'s manufacturer, were not amused, and the name was subsequently changed to Wrinkle Relax. The cream is designed to minimize facial contractions using naturally derived amino acids to block nerve impulses that initiate contractions. The line's founder, Howard Sobel, M.D., stresses that this cream doesn't replicate **Botox**'s immediate effects--to do so, it would have to be injected directly into the muscle--but adds that unlike **botulinum** toxin, these formulas are nontoxic, easing that common worry among users.

Even the big guns have jumped on the **Botox** bandwagon: Lancome with Resolution D-Contraxol Intensive Anti-Wrinkle Treatment and Helena Rubinstein with Expressionist. Both products are positioned as noninvasive treatments to target "dermocreasing"--Lancome's catchy term for the lines and wrinkles that develop over the years when faces do what they do.

For the scientists at Lancome, it was the discovery of actin and myosin that begat Resolution. These fibers are found within the skin's collagen- and elastin-producing cell, the fibroblast. "We discovered the inner workings of the fibroblast," explains Alan J. Meyers, vice president of central research for L'Oreal USA, "and we learned that as we age, these fibers become as tight as a fist, therefore not allowing the fibroblast to return to its original shape." Armed with this information, the team formulated Resolution with D-Contraxol, a mineral complex that the company daims relaxes the actin and myosin and, in turn, the skin itself, making it less apt to tense up into a wrinkle or line.

Arguing that facial muscles contract more when calcium is present within fibroblasts, Helena Rubinstein has used a combination of minerals and amino acids in Expressionist to encourage calcium absorption, thereby slowing down and softening excess muscle movement.

Rubinstein's assistant vice president of research and development, Maria Ulrich, stresses that this product won't replace **Botox** injections since it is intended not to eliminate deep wrinkles, but to stop them from forming at the first signs of expression lines. DDF's Sobel adds, "These creams are helpful for people averse to needles or for those who want to perpetuate the effects of the injections."

ENERGY CRISIS

Somewhere between the tidy boundaries that define traditional skin care categories (normal, dry, oily) lurks an increasingly relevant new

classification, one that can be attributed to modern-day living. Some experts refer to it as "energy-deprived" skin, while others simply call it "fatigued."

"With Repairwear, we figured out how to build protection by building energy" says Ken Marenus, Ph.D., vice president of biological research for Clinique. According to Marenus, Repairwear works via its Vital Fuel Complex, made up of a medley of plant and marine extracts that he says replicates AIP's energizing powers. Also, he adds, using Repairwear at night, while the body is in a restful state, optimizes the results. (See "Rest Assured," below, for more on sleep and the skin)

New skin tools are targeting this energy depletion--which is brought on by today's abundant stress, pollution and UV exposure, resulting in sallowness, dullness and sagging--in different ways. Some, like Clinique's Repairwear family of products (a night cream, lotion and Extra Help Serum), aim to get to the root of the problem by replenishing the skin's levels of ATP (adenosine triphosphate), which is responsible for cells' energy-making capabilities.

The researchers behind the French spa line Sothys likewise believe in the importance of boosting ATP production; their mission is to help the skin cells better utilize the body's internal oxygen supply and, yes, produce ATP. According to Charles Mizelle, director of regional operations for Sothys, the marine ingredients in the Sothys Oxyliance collection--a mask, serum, cream and lotion--are proven to increase cellular oxygen levels. "This system is like a cardio workout for the skin cells," he says. "It will boost metabolism and expel toxins, all resulting in an energized skin." He adds that it is ideal for "city skin, smokers' skin and asphyxiated skin"

Indeed, short of never leaving the house (or never losing your cool), these peppy skin care offerings might deliver the best protection against the damages of daily life.

A FLUSH WITH GREATNESS

For some women, a radiant complexion is attainable only on a few fleeting occasions: during pregnancy, for example, or just after a workout. But rosy cheeks, clarity and balanced skin tone are universal goals.

"Without question, one of the most common requests we get is to get the glow back," says Soren M. White, M.D., clinical director of New York's SkinKlinic. "Loss of radiance can be filed into two categories: intrinsic aging, which simply happens to skin over time; the other is sun exposure, which is responsible for extrinsic aging. There's an overlap between the two in that sun exposure speeds up collagen loss and the breaking down of elastin fibers, not to mention the increased pigmentation of skin."

While White recommends in-clinic treatments such as glycolic peels or laser resurfacing, skin care companies are constantly whipping up recipes to get the glow back at home. Theorizing that slow blood circulation beneath skin's surface is to blame, Chanel created Radiance Revealing Serum with a plant-based complex that mimics the action of a protein responsible for jump-starting said blood flow. Researchers at Olay blame dullness on slow turnover of surface skin cells, so its new Regenerist, with an Amino-Peptide Complex that is full of vitamins and green tea extract, strengthens skin's outer layer and increases cell turnover. And Estee Lauder uses a highly secretive BioSync Complex that encourages collagen and elastin production to bring about a smoother texture while its lipid complex pumps up the radiance factor.

Meanwhile, Biotherm aims for that coveted luminosity with its new Pure Bright collection, including Illuminating Essence, a serum containing kojic acid, which suppresses melanin production. Excess melanin is the main culprit behind uneven skin tone, dark spots and ***freckles***. Additionally, tiny mica mineral crystals in the serum help give a balanced glow.

The clear-as-crystal concept is also in Re Vive's Intensite, in which micas are coated with an ultrafine acrylic for that soft-focus effect along with an insulin-like growth factor that helps strengthen skin's structure. Lierac's Sequential goes for the glow by packing its recipes with

hyaluronic acid and vitamins A, C and E, along with--deep breath--copper, calcium, magnesium and zinc. Not to mention a patented delivery system that carries the ingredients in a molecule form to penetrate deeper into skin. The result? Faster collagen production. And while the hormone DHEA has been used in skin care for its anti-aging properties, Yves Saint Laurent uses a plant component, Ganoderma, in its Age Defying Creme to mimic DHEA in keeping sebaceous glands active in skin that becomes drier with age. Straddling the line between skin care and makeup is La Prairie's new Cellular Treatment Rose Illusion, a prefoundation prep that temporarily smoothes over lines and wrinkles, with additional optical diffusers to soften skin 's appearance.

But perhaps the most intriguing radiance activator is from Guerlain. Running with the joyful fact that chocolate causes the brain to produce endorphins, which prompt good feelings, Guerlain has recently discovered that endorphins also boost skin cell activity. The Paris-based company is hoping to mimic that effect in its new Happylogy Glowing Skin Treatment. The magic comes from a Pro-Endorphin Complex that, along with antioxidants, contains--you guessed it--a cocoa extract known to help boost endorphin production.

ADVANCED CHEMISTRY

Science is the gift that keeps on giving. These latest discoveries are set to influence the product formulations of the future.

Spin Traps: This new category of antioxidants is likely to steal the show in the next few years. Free radicals are incomplete atoms that prey on healthy cells for their missing link, thus blazing a warpath of destruction (showing up as aging skin). While most antioxidants work by neutralizing free radicals, a spin trap actually traps them and reforms them to do good. Once a free radical is spin-trapped, it's preserved, charged with energy and dumped back into the respiratory cycle, where it helps to build up the body's natural defenses.

In October, at the American Academy of Dermatology annual meeting, dermatologist Patricia Farris of Tulane University School of Medicine stated that spin traps are on the cutting edge of skin care. Even dermatologist Nicholas Perricone praises spin traps' anti-inflammatory properties (his translation: fewer wrinkles) in his wildly successful book, The Wrinkle Cure. Many professionals are still skeptical and await more proof of the ingredients' efficacy but Lynn Ross, president of Institut' DerMed, a cosmeceutical line that contains spin traps, is already convinced. "We have new information and ingredients at our disposal, so we should use it," she says. "I'm not going to let myself age like my grandmother."

Chiral Technology: First discovered by Louis Pasteur more than a century ago, chiral technology is the separation of a single molecule into two halves--right and left, like a pair of hands. (The Greek word for hand is chir, hence the name chiral) Chirally correcting a molecule involves removing the half with negative properties, leaving only the positive half. The FDA recently mandated that, when possible, all new pharmaceuticals be chirally correct, in an effort to decrease side effects. (Some existing drugs aren't chirally correct: Ibuprofen, for example, contains isomeric molecules that ease body pain, but many people experience nausea because of its negative side.)

Only recently has chiral technology been incorporated in skin care. "Applying this concept to skin care makes sense," says Michael Wolfgeher, president of Sircuit Cosmeceuticals, a new line of chirally correct skin care products based in California. Wolfgeher argues that a product with chirally correct molecules is more potent than one that isn't. "More targeted benefits are achieved so you can really utilize the ingredients," he says. "Once you understand that this is the way the world is going to be working eventually--with food, with drugs--it just makes common sense."

REST ASSURED

Yes, there really is such a thing as beauty sleep--and as skin care companies learn more about its benefits, they're introducing a slew of new nighttime formulations.

"At night, your skin isn't sleeping, it's repairing," says Clinique's Marenus. Inspired by new research linking plentiful sleep to improved skin quality, the company's Repairwear collection was specifically designed to energize skin during the night's rest. According to Marenus, nighttime is when the skin takes a virtual deep breath, addressing the day's damage and arming itself for the next morning. Think of sleep as a hyperefficient housekeeper, cleaning supplies in hand, who shows up to tidy everything with nary a complaint.

Another skin care company ready to heat up the night is Clarins, with its Line Prevention Multi-Active Night Cream. Working on the premise that at night the skin experiences a decrease in cortisol hormone, the new product aims to boost levels with a botanical equivalent that includes English oak root, a skin smoother with a built-in free radical defense mechanism. "As cortisol levels lower, your skin becomes more susceptible to inflammation and irritation," explains Caroline Pieper-Vogt, vice president of marketing at Clams. At night, the skin also experiences extreme water loss, which Line Prevention also addresses.

"The skin cells must be saturated with the relief substances they need to breathe freely, rebuild their stocks, recover and renew," adds Pieper-Vogt. All while you're fast asleep.

TEXT:

To maintain a healthy, youthful appearance, dermatologic surgeons often start their patients on a skin-care regimen to treat the milder symptoms of aging. In subsequent decades, they progressively choose from their treatment repertoire to correct the deeper, more advanced signs of the aging face. Here's what to watch for:

The 20s. While most people enjoy beautiful skin throughout their 20s, fine lines, ***freckles***, and other cosmetic flaws may begin to appear. Prescription creams and lotions, light chemical peels, and certain resurfacing techniques like microdermabrasion can stave off these blemishes, while setting the stage for a youthful look in the years ahead.

The 30s. Wrinkles, brown spots, broken veins, some thinning here, some thickening there -- this is typically the decade when the aging process gradually begins to show. Soft-tissue fillers, ***botulinum*** toxin therapy, chemical peels, and laser treatments are some popular procedures to repair damage to the skin's top layers and underpinnings.

The 40s. Once the beginning of the end, this decade is now considered the peak of physical and personal confidence. While excess hair, stubborn fat deposits, wrinkles and creases, sagging jowls or baggy eyelids will undoubtedly appear, they can be erased by more intensive applications of many of the same treatments, along with additional procedures like liposuction using local anesthesia, laser resurfacing, laser hair removal, blepharoplasty, and dermabrasion.

The 50s and beyond. Yes, it is possible to have smooth, luminous skin in these years, especially for people who have enjoyed early intervention in the preceding decades. Thanks to the effectiveness of today's arsenal of

skin rejuvenation procedures, even deep-set lines and wrinkles, the accumulation of pigmentation changes, loose skin, and fat loss can be dramatically improved and recontoured. Often, a combination of treatment options is recommended to enhance elderly skin.

In this article, the most common cutaneous manifestations of photodamage and chronological aging, with the exception of invasive malignancies, are reviewed. Current nonsurgical approaches to the amelioration of the manifestations are discussed, including application of various topical preparations, noninvasive physical and chemical procedures for removal of proliferative lesions, and the options for soft-tissue augmentation.

Aged skin is the result of the combined processes of intrinsic aging and photoaging. Intrinsic aging is a cellular process that involves the accumulation of chronological genetic changes. Little is understood about how to combat intrinsic aging. Photoaging involves environmental effects, mainly damage from the sun, that can be reduced through a variety of interventions. Several options exist for improving the appearance of aging skin. We present information about the use of nonablative intense pulsed light technology in addition to **botulinum** toxin type A for eradication of the signs of photoaged skin. A structured clinical approach is outlined.

Background and Objectives: Non-ablative technologies are playing an increasing role in the management of photoaging. Newer radiofrequency technologies have added to this therapeutic armamentarium. Shorter wavelength technologies are more effective in targeting pilosebaceous vascular and pigmentary alterations while longer wavelength technologies are most effective in wrinkle reduction mediated through dermal remodeling. An overview of the various technologies available to the practicing laser surgeon are outlined in the present review. (c) 2003 Wiley-Liss, Inc.
